## Switch Case :

The 'switch case' statement is like the 'if... else' statement but a cleaner and quicker way than 'if... else'. It is present in languages like C++ or Java.

We use switch case specifically, when we need to run only a specific code block, and if the other code blocks do not satisfy the condition, they will be skipped. If this code block is checked manually, the complexity of code increases making it unfavorable.

Using a switch case statement, one can test a variable for being one of the many possible values. The variable will follow the code for the particular value it takes. The significance of the switch case statement includes-

- Easy debugging
- Easy to read and understand
- Easy to maintain
- Easy to verify the values to be checked and handled

## Syntax:

```
match term:
    case pattern-1:
        action-1
    case pattern-2:
        action-2
    case pattern-3:
        action-3
    case _:
        action-default
```

Note that the underscore symbol is what you use to define a default case for the switch statement in Python.

An example of a switch statement written with the match case syntax is shown below. It is a program that prints what you can become when you learn various programming languages:

```
lang = input("What's the programming language you want to learn? ")
```

```
match lang:
```

```
case "JavaScript":
```

```
    print("You can become a web developer.")
```

```
case "Python":
```

```
    print("You can become a Data Scientist")
```

```
case "PHP":
```

```
    print("You can become a backend developer")
```

```
case "Solidity":
```

```
    print("You can become a Block chain developer")
```

```
case "Java":
```

```
    print("You can become a mobile app developer")
```

```
case _:
```

```
    print("The language doesn't matter, what matters is solving problems.")
```
